Bootstrap for sampling distribution of sample mean

Assessing assumptions

- Our t-tests assume normality of variable being tested
- but, Central Limit Theorem says that normality matters less if sample is "large"
- in practice "approximate normality" is enough, but how do we assess whether what we have is normal enough?
- so far, use histogram/boxplot and make a call, allowing for sample size.

What actually has to be normal

- is: sampling distribution of sample mean
- the distribution of sample mean over all possible samples
- but we only have one sample!
- ▶ Idea: assume our sample is representative of the population, and draw samples from our sample (!), with replacement.
- This gives an idea of what different samples from the population might look like.
- Called bootstrap, after expression "to pull yourself up by your own bootstraps".

Packages

library(tidyverse)

Blue Jays attendances

jays\$attendance

- [1] 48414 17264 15086 14433 21397 34743 44794 14184 15606 [13] 21312 30430 42917 42419 29306 15062 16402 19014 21195 [25] 17276
- A bootstrap sample:

```
s <- sample(jays$attendance, replace = TRUE)
s</pre>
```

[25] 30430It is easier to see what is happening if we sort both the actual

[1] 21195 34743 21312 44794 16402 19014 34743 21195 17264 [13] 34743 19217 14433 15062 16402 15062 34743 15062 15086

attendances and the bootstrap sample:
sort(jays\$attendance)

[1] 14184 14433 15062 15086 15168 15606 16402 17264 17276

Getting mean of bootstrap sample

- A bootstrap sample is same size as original, but contains repeated values (eg. 15062) and missing ones (42917).
- We need the mean of our bootstrap sample:

mean(s)

[1] 23055.28

This is a little different from the mean of our actual sample:

mean(jays\$attendance)

[1] 25070.16

- ▶ Want a sense of how the sample mean might vary, if we were able to take repeated samples from our population.
- ▶ Idea: take lots of bootstrap samples, and see how their sample means vary.

Setting up bootstrap sampling

Begin by setting up a dataframe that contains a row for each bootstrap sample. I usually call this column sim. Do just 4 to get the idea:

```
# A tibble: 4 x 1
    sim
    <int>
1    1
2    2
3    3
4    4
```

Drawing the bootstrap samples

Then set up to work one row at a time, and draw a bootstrap sample of the attendances in each row:

```
tibble(sim = 1:4) %>%
  rowwise() %>%
  mutate(sample = list(sample(jays$attendance, replace = T)

# A tibble: 4 x 2
# Rowwise:
    sim sample
```

- - ▶ Each row of our dataframe contains *all* of a bootstrap sample of 25 observations drawn with replacement from the attendances.

Sample means

4

Find the mean of each sample:

4 <dbl [25]> 24808.

```
tibble(sim = 1:4) %>%
 rowwise() %>%
 mutate(sample = list(sample(jays$attendance, replace = T)
 mutate(my_mean = mean(sample))
# A tibble: 4 \times 3
# Rowwise:
   sim sample my_mean
 <int> <dbl>
 1 <dbl [25]> 28472.
 2 <dbl [25]> 28648.
3
  3 <dbl [25]> 23329.
```

► These are (four simulated values of) the bootstrapped sampling distribution of the sample mean.

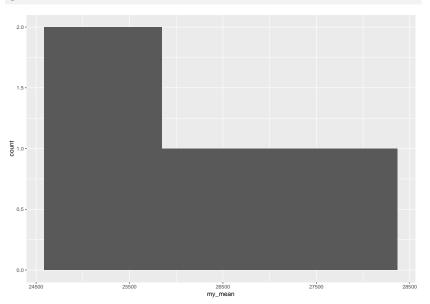

Make a histogram of them

rather pointless here, but to get the idea:

```
tibble(sim = 1:4) %>%
  rowwise() %>%
  mutate(sample = list(sample(jays$attendance, replace = T)
  mutate(my_mean = mean(sample)) %>%
  ggplot(aes(x = my_mean)) + geom_histogram(bins = 3) -> g
```

The (pointless) histogram

g

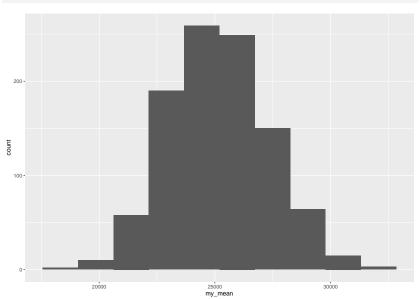

Now do again with a decent number of bootstrap samples

say 1000, and put a decent number of bins on the histogram also:

```
tibble(sim = 1:1000) %>%
  rowwise() %>%
  mutate(sample = list(sample(jays$attendance, replace = The mutate(my_mean = mean(sample)) %>%
  ggplot(aes(x = my_mean)) + geom_histogram(bins = 10) -> geom_histogram(bins = 10)
```

The (better) histogram

g

Comments

- This is very close to normal
- ➤ The bootstrap says that the sampling distribution of the sample mean is close to normal, even though the distribution of the data is not
- ▶ A sample size of 25 is big enough to overcome the skewness that we saw
- This is the Central Limit Theorem in practice
- It is surprisingly powerful.
- ightharpoonup Thus, the t-test is actually perfectly good here.

Comments on the code 1/2

4 <dbl [25]>

4

You might have been wondering about this:

```
tibble(sim = 1:4) %>%
 rowwise() %>%
 mutate(sample = list(sample(jays$attendance, replace = T)
# A tibble: 4 x 2
# Rowwise:
   sim sample
  <int> <list>
    1 <dbl [25]>
 2 <dbl [25]>
2
3
   3 <dbl [25]>
```

Comments on the code 2/2

- how did we squeeze all 25 sample values into one cell?sample is a so-called "list-column" that can contain anything.
- sample is a so-called list-column that can contain anything
- why did we have to put list() around the sample()?
 - because sample produces a collection of numbers, not just a single one
 - the list() signals this: "make a list-column of samples".

Two samples

- Assumption: both samples are from a normal distribution.
- In this case, each sample should be "normal enough" given its sample size, since Central Limit Theorem will help.
- Use bootstrap on each group independently, as above.

Kids learning to read

```
# A tibble: 44 x 2
  group score
  <chr> <dbl>
 1 t
           24
2 t
          61
3 t.
         59
4 t
         46
5 t
         43
6 t
         44
7 t.
         52
8 t.
         43
9 t
           58
10 t
           67
# i 34 more rows
```

ggplot(kids, aes(x=group, y=score)) + geom boxplot()

Getting just the control group

▶ Use filter to select rows where something is true:

```
kids %>% filter(group=="c") -> controls
controls
```

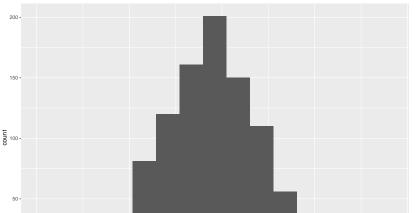

```
# A tibble: 23 \times 2
  group score
  <chr> <dbl>
1 c
          42
2 c
        33
3 c
       46
4 c 37
5 c 43
6 c
    41
7 c
        10
8 c
          42
9 c
          55
10 c
          19
# i 13 more rows
```

Bootstrap these

```
tibble(sim = 1:1000) %>%
 rowwise() %>%
 mutate(sample = list(sample(controls$score, replace = TR)
 mutate(my mean = mean(sample)) %>%
 ggplot(aes(x = my_mean)) + geom_histogram(bins = 10)
 300 -
 200 -
```

... and the treatment group:

```
kids %>% filter(group=="t") -> treats
tibble(sim = 1:1000) %>%
   rowwise() %>%
   mutate(sample = list(sample(treats$score, replace = TRUE)
   mutate(my_mean = mean(sample)) %>%
   ggplot(aes(x = my_mean)) + geom_histogram(bins = 15)
```

Comments

- sampling distributions of sample means both look pretty normal, though treatment group is a tiny bit left-skewed
- lacktriangle as we thought, no problems with our two-sample t at all.
